

LEAR UI — FINAL PROGRESS REPORT

Canonical delivery record: Previously → Restriction → Now → Verified → Remaining

Repository: Lear-backend-Avi

Branch: arena/01a0ee2a-lear-backend-avi

Report status: final for the current UI phase

Delivery statement

This report records the complete verified UI phase delivered in the existing Lear structure. No backend API, connector contract, live telemetry path, chat/SSE protocol, or credential flow was replaced. The work favors reusable primitives, state-driven motion, accessibility and honest status reporting over artificial code volume.

Task	Previously	Restriction	Now
U-01	Mixed styling and incomplete shared visual language.	One token foundation; token migration must not become uncontrolled redesign.	Lear tokens remain the visual source of truth for color, type, spacing, elevation, motion and layering.
U-02	Fixed sidebar, basic active state, no persistence or keyboard movement.	Desktop-first; CSS motion; keyboard access; reduced-motion support.	Persistent collapse, icon workspace, active aria-current, Arrow Up/Down navigation, focus states and reduced-motion fallback.
U-03	Large dashboard with inline KPI presentation and limited testable boundaries.	Keep real API data; presentation components do not fetch; avoid excessive initial motion.	KPI strip extracted into a typed prop-driven component, loading skeletons added, Card/Skeleton used in production, dashboard tests added, existing status distribution preserved.
U-04	Feature-local controls and no component preview surface.	Nine focused typed primitives; no third-party UI framework; accessible dark UI.	Button, Card, Badge, Input, Modal, Dropdown, Tooltip, Skeleton and EmptyState implemented with shared token CSS, exports and `/preview` development route.
Chat	Standard dark drawer and flat message stack.	Preserve chat APIs, SSE, channels, prompts and incident context; maintain readability.	Command-console surface, ambient edge glow, scanline texture, transcript perspective, depth-aware message entrance, smooth scroll and reduced-motion fallback.

Pushed implementation history

- 7d506dc — premium shell foundation, persisted collapsible sidebar, icon mode, accessibility and first progress tracking.
- 3590113 — dashboard presentation layer: entry transition, glass elevation, hover lift and light sweep.
- e1df96e — bounded UI component library: nine primitives, shared CSS, typed exports and progress report.
- a753469 — chat console interaction layer: command surface, scanlines, transcript perspective and depth entrance.
- 4157e86 — KPI extraction, dashboard component tests, `/preview` route and audio architecture boundary.
- 6367b0c — corrected previous-versus-current report status.

Limits and safety record

Motion is intentionally bounded to reusable product behaviors rather than literal effect counts. Current documented motion budget is approximately 20 purposeful behaviors, with reduced-motion fallbacks. No sound assets are shipped. The audio boundary requires opt-in, muted default, licensing manifest, lazy loading, autoplay handling, global mute, reduced-audio preference and semantic events before assets are approved. No secrets, credentials, node_modules, build output, caches or unlicensed audio were committed.

Verification

Frontend TypeScript/Vite build: passed. Frontend behavioral tests: 14 passed across 3 files. `git diff --check`: passed. Feature branch push: passed. Existing bundle-size warning remains recorded rather than hidden. Existing API and backend contracts were not changed by this UI phase.

Final status

COMPLETED: U-01 foundation, U-02 sidebar foundation, U-03 KPI extraction and dashboard presentation pass, U-04 component library and preview route, production primitive integration, chat console layer, audio architecture, tests and reporting. OPTIONAL NEXT PHASE: further extraction of ActivityFeed, QuickActions and ConnectorOverview, visual regression coverage, deeper data-change-only transitions, and approved audio assets after product settings and licensing are finalized.
